

ABSTRACT

A buffer device (1) receives unit information from a server (2), stores delivery destination information that relates to the destination of a delivery for each delivery destination, and also stores additional information that is to be added to the unit information. Based on the delivery destination information as well as unit attribute information that relates to time spans and attributes of the received unit information, the buffer device (1) then creates transmission information that instructs that the stored additional information is to be added to the received unit information and then transmitted. Based on the created transmission information, the buffer device (1) then adds the stored additional information to the received unit information and transmits the unit information to which the additional information has been added to the terminal (4).
